

Tell me about yourself and your experience relevant to a **tech support role**.

Hello, my name is Vedant. I am currently pursuing B.Tech in Computer Science with a specialization in AI.

I have hands-on experience in building machine learning models, working with data pipelines, and applying data science concepts, which has strengthened my analytical and problem-solving skills.

Along with technical skills, I have actively developed my communication and leadership abilities through roles like Campus Ambassador at GeeksforGeeks and EDC Cell IIT Delhi, and as a contributor in GSSOC.

I am also an active member of my college coding club, where I help peers with coding and technical doubts, which has improved my ability to explain technical concepts clearly—an important skill for a support role.

I am now looking to apply my technical and communication skills in a tech support role where I can help users troubleshoot issues and ensure smooth system performance.

2, Imagine a user reports:

“The application is not loading on my system.”

What steps would you take to troubleshoot this issue?

First, I would clarify the issue by asking the user when the problem started, what exact error they see, and whether it is consistent or intermittent.

Then I would try to reproduce the issue in a staging environment to isolate whether it is user-specific or system-wide.

After that, I would check logs using tools like grep and awk to trace the failure point, and review API responses or backend logs if applicable.

I would also validate inputs such as JSON, XML, or CSV payloads to check for missing fields or formatting issues.

If it is an HTTP-related issue, I would interpret status codes—for example, 4xx for client-side issues like authentication or bad requests, and 5xx for server-side issues.

Once the root cause is identified, I would document it, communicate with the engineering team if needed, and ensure the fix is validated before closing the ticket.

Question 3 (follow-up, more realistic support scenario):

A user says:

“I can log in, but after login the dashboard is completely blank.”

How would you troubleshoot this step by step?

First, I would ask clarifying questions such as whether the issue is consistent, when it started, and whether it happens for all users or only a specific user or role.

Then I would try to reproduce the issue in a staging or test environment to check if it is user-specific or system-wide.

Next, I would check browser-level diagnostics like the console and network tab to see if API calls are failing, returning empty responses, or if there are JavaScript errors causing the dashboard not to render.

I would also verify authentication tokens, session validity, and user permissions since a blank dashboard can often result from authorization or data access issues.

On the backend side, I would review logs to identify failed API calls or missing data responses. If APIs are returning 4xx or 5xx errors, I would further isolate whether it is a client-side request issue or a server-side failure.

If it is a backend issue, I would escalate it to the engineering team with logs and reproduction steps.

Finally, I would keep the customer updated regularly based on severity and ensure the issue is tracked until resolution.

Question 4 (behavior + real support thinking):

A customer is **angry and says:**

“Your system is useless. This issue is affecting my business and no one is helping me!”

How would you handle this situation both technically and emotionally?

First, I would let the customer explain the issue completely without interrupting, and I would acknowledge their frustration by saying I understand this is impacting their business and I will help them resolve it as quickly as possible.

Then I would ask focused clarifying questions to understand the exact issue, such as when it started, how many users are affected, and what changes were made before the issue occurred.

After that, I would start initial troubleshooting by checking logs, recent deployments, and system health to identify whether it is a client-side, configuration, or backend issue.

If I find it is a backend issue beyond support scope, I would immediately escalate it to the engineering team with all relevant details like logs, timestamps, and reproduction steps.

At the same time, I would keep the customer informed with clear and honest updates, setting expectations on next steps and resolution time.

My goal would be to not only resolve the issue but also ensure the customer feels heard, supported, and confident that the issue is being handled seriously.

5. A customer reports:

“Data is missing in my report dashboard, but it was working fine yesterday.”

How would you approach this issue step by step in a production support environment?

First, I would ask clarifying questions such as which specific report is affected, whether all users are impacted, and what time range is selected. I would also check if any recent changes or deployments occurred before the issue started.

Then I would try to reproduce the issue in a staging environment to confirm whether it is system-wide or user-specific.

Next, I would investigate the data flow step by step—starting from data ingestion to processing and then API response—to identify where the breakdown is happening.

I would check logs using tools like grep and tail to identify any ingestion failures, ETL job errors, or API response issues. I would also verify whether the database is receiving and storing the data correctly and whether any filters or date ranges are affecting the output.

If the issue is not within the support scope or requires code-level fixes, I would escalate it to the engineering team with detailed logs, timestamps, and reproduction steps.

Finally, I would keep the customer informed about progress and expected resolution timelines.
